

ABSTRACT OF DISCLOSURE

1 The apparatus is connected to a member on the elevator that moves if and when the slips
2 move between the open and closed positions. The member is locked in a preselected position that
3 attends the position of the slips when the elevator is considered safe. When the member is in that safe
4 position a wireless signal is generated by the apparatus part on the elevator and received by a
5 receiving part of the apparatus in a convenient remote location such as the drillers position. In
6 response to the received signal, the receiving part produces a visible signal to indicate that the slips
7 are in the preselected position.
